The boundary element method attempts to use the given boundary conditions to fit boundary values into the integral equation, rather than values throughout the space defined by a partial differential equation. Once this is done, in the post-processing stage, the integral equation can then be used again to calculate numerically the solution directly at any desired point in the interior of the solution domain.

Boundary element method - Wikipedia

The finite element method formulation of a boundary value problem finally results in a system of algebraic equations. The method approximates the unknown function over the domain. The simple equations that model these finite elements are then assembled into a larger system of equations that models the entire problem.

Finite element method - Wikipedia

Written by two well-respected experts in the field, The Finite Element Method for Boundary Value Problems: Mathematics and Computations bridges the gap between applied mathematics and application-oriented computational studies using FEM. Mathematically rigorous, the FEM is presented as a method of approximation for differential operators that are mathematically classified as self-adjoint, non-self-adjoint, and non-linear, thus addressing totality of all BVPs in various areas of engineering. ...

The Finite Element Method for Boundary Value Problems -

The finite element method (FEM), or finite element analysis (FEA), is a computational technique used to obtain approximate solutions of boundary value problems in engineering. Boundary value problems are also called field problems. The field is the domain of interest and most often represents a physical structure.

The finite element method (FEM) is used to compute such approximations. Take, for example, a function u that may be the dependent variable in a PDE (i.e., temperature, electric potential, pressure, etc.) The function u can be approximated by a function u_h using linear combinations of basis functions according to the following expressions: (1)

We wish to find then a 1 time-dependent solution vector $u(t)$ to the ODE system. $M\dot{u}(t)+A u(t)=b(t); 0 < t < T$ (5.1a) $u(0)=u_0$ (5.1b) where \dot{u} means differentiation with respect to time t , T is the final time, M and A are given constant $n \times n$ matrices, $b(t)$ is a given time-dependent $n \times 1$ vector, and u_0 is given $n \times 1$ vector with initial data.

Boundary Conditions The main types of loading available in FEA include force, pressure and temperature. These can be applied to points, surfaces, edges, nodes and elements or remotely offset from a feature. The way that the model is constrained can significantly affect the results and requires special consideration.

As you may know, in finite element method first we make stiffness matrix (or global coefficient matrix from local coefficient matrix). Then we apply our governing equation (here the Laplace equation).

Numerical methods have been widely used in engineering due to their feasibility and reliability in handling problems with complex geometries and boundary conditions. The finite element method (FEM) is one of the most popular numerical method, in which a problem domain is spatially discretized into small subdomains with simple shapes, called elements.
